

Handoff — paste this into the new session

Session ran 2026-08-22, 05:40 to ~15:45 EDT. Nothing below needs the old transcript. Every claim here was verified at 15:45, not recalled.

Read this first: yesterday's handoff lied, and that is the lesson

The previous handoff stated things that were false — that M4 was at 0%, that a branch was unpushed when it was pushed, that a cleanup was complete when it was not. Three separate wrong claims, each written from memory rather than measurement, each of which cost real time today.

So: verify before you assert. `gh api`, `git log`, `milestone-bars`. If you find something in this file that does not match the repository, the repository is right.

State, measured at 15:45

<code>tom2025b/Git-Vista</code>	PUBLIC (flipped today), 0 forks, 0 stars
Actions	enabled, and free now the repo is public
<code>main</code>	<code>3a562941</code> , clean tree, gate green and gatehouse-verified
M4	55.6% — 5 shipped, 4 open, 2 cut
global <code>user.email</code>	<code>262510778+tom2025b@users.noreply.github.com</code>

What shipped today

PR	What
435	<code>fix(#434)</code> the gate can fail again + ADR 0065
437	<code>fix(#436)</code> the frontend compiles again
439	M4.31a (#428) inspect a conflict — four panes + ADR 0066
440	M4.31b (#429) whole-file resolution + ADR 0067
441	<code>chore</code> redact the personal email from tracked docs

Next work: the rest of M4.31

Three sub-issues remain under #84.

1. **#430 — M4.31d, binary/rename/delete UX.** The natural next one. `NotTextResolvable` already models all three cases; this is rendering them distinctly instead of lumping them together. Low risk, and #428/#429 built the surface it renders into.
2. **#431 — M4.31e, survives reconnect and crash.** Medium. Leans on the operation lifecycle rather than on new conflict logic.
3. **#432 — M4.31c, block and line resolution + manual editing. Needs an ADR before any code.** It carries file content through a `Plan`, which is hashed, reviewed and replayed. Fable's independent review already exists:
`~/projects/_claude-outputs/2026-08-22_fable-conflict-content-transport.md`. Its sharpest finding: an editor seeded from the working-tree marker file is invisible to both the

porcelain generation and the index checksum, so it must be digested into a `conflict-v1:` token the way `diff-v1:` digests patch bytes.

Then #84 closes and M4 finishes.

Loose ends

- `ci/allow-manual-dispatch` **is committed locally but NOT pushed**. GitHub refused it: this token lacks the `workflow` scope, so it cannot push changes under `.github/workflows/`. Tom pushes it himself, or drop it — it only adds `workflow_dispatch`.
- **CI proven working post-quota, 2026-08-22**. Tom re-ran the stuck 08-20 scheduled run by hand (attempt 2, `run_started_at` 20:00 UTC) — all 7 jobs green with real durations (10s-13m43s), not the 4-second zero-step shape. Run: github.com/tom2025b/git-vista/actions/runs/32337083677. One caveat: the workflow file on `main` still only triggers on `push/pull_request/` `schedule` — `workflow_dispatch` (the pending `ci/allow-manual-dispatch` commit, unpushed, needs the `workflow` token scope) is still not there, so today's re-run worked because an *existing* run could be manually re-run, not because on-demand triggering exists yet.
- **Secret scanning + push protection are OFF** and are **free on public repos**: github.com/tom2025b/Git-Vista/settings/security_analysis. Push protection is the guard that would have stopped the committed sign-in tokens. Worth suggesting once.
- **#438**, flaky: `recovery_center::a_stale_claimed_undo_is_refused...` fails roughly one full-suite run in three. Found by the repaired gate.
- **~929 MB of build artifacts** in history on two feature branches. Not in any current tree, so a normal clone does not fetch it.

- `backupsage` is public with one gmail-authored commit (bd50e227, April 8). Tom's call whether to care.

The privacy incident — settled, do not re-litigate

Half of today went to this. It is closed. Do not reopen it, and do not repeat the wrong versions:

- **No credential was ever leaked.** Three independent scanners agree: max's pattern scan, fable's object-database scan, and `gitleaks` over 3,436 commits. Sign-in tokens *were* committed in console logs — Tom's memory was right — but they are single-use, already redeemed, loopback-only, and not reachable from any ref GitHub serves. **Nothing to rotate.**
- **The root cause was the global git config**, which still said `thomaslane2025@gmail.com` and was inherited by 39 of 50 repos. Fixed today. That is why every prior cleanup "failed": they scrubbed output and left the tap running.
- **CLAUDE.md's never-touch-the-global-config rule is obsolete** — it existed to protect Tom's name on his own commits, and `user.name` is still `tomb`.
- **The guard hook was blocking 6 of 13 commit paths.** `rebase`, `merge`, `cherry-pick`, `revert`, `stash` and `am` all walked past it, and `rebase` re-stamps the committer on every replayed commit — which is why ~149 commits became 298 identity occurrences. Now 12 of 13. Probe: `/tmp/claude-1000/hookprobe.py`.
- **CLAUDE.md says "91 commits on a public main."** The real number was 298 identity occurrences. Both max and fable measured it. The file is stale.
- **Tom retired the old address from GitHub** and hardened his Google account (60 → 17 OAuth grants, new password, new recovery email, landline recovery phone, regenerated backup

codes on paper, passkeys). The addresses left in history are inert strings.

Two corrections worth carrying forward

Both came from Tom saying "**check it a different way.**" It changed the answer both times:

- The `backup/main-with-gmail-2026-08-04` branch was described as a redundant gmail archive. It is not: 379 commits, 364 already on a local branch, and the **15 unique ones are all clean noreply**. Deleting it would have cost commits and bought zero privacy. **Kept.**
- Deleting the 1,110 `refs/replace/*` removed the *index*, not the *objects*. Verified afterwards: GitHub still serves commit `004c1136` by SHA, authored with the gmail. A real reduction, not a fix. The 230 `refs/pull/*` are GitHub-managed and undeletable.

How to work here

- `./dev gate` **can fail again** (#434/ADR 0065). Trust it now. Prove it with `ci/gate_errexist_test.sh`.
- `./dev browser` **does NOT run trunk build**. Run trunk first or you test a stale bundle.
- **Merged is not deployed.** `trunk build` rewrites `crates/git-vista/dist/`; a hard reload reaches Tom. Never restart the server on 8080 — it rotates his token.
- `buildlock` **every cargo/trunk invocation.**
- **A WIP checkpoint owns the git index.** Do not fight it; it commits on a timer.
- **Mutations: two minimum, failing differently.** Today one survived and exposed a genuinely inert test (`with_content`'s guard, only the `0k` path tested). Another survived and drove a

design change: a handler-side `WorktreePath::new` call was skippable, so the DTO field became a `WorktreePath` and the check is now structural.

- **Say when a stretch is docs-only** so Tom can drop to a cheaper model. This was not done today and it cost him money. ADRs, briefs, PR bodies, issue bodies — all prose.

Tom, right now

He was exposed by repeated Claude failures and was rightly furious. He is calm now and the incident is resolved, but **do not be breezy about security here** — he was seriously compromised in 2023 across several devices. Name the surface, say who it opens it to, and say what still holds.

What he actually wants: **his work public, with credit**. Git-Vista is public as of today. `linux-ops-suite`, `backupsage` and the MCP repos are candidates he has named.
