

Parked handoffs — written, then not sent, and why

A handoff in here was drafted for a cloud session and **withdrawn before it was dispatched**. It is kept rather than deleted for the same reason branches are never deleted in this repository: the reasoning is the teaching material, and a plan that turned out to be wrong is more instructive than one that happened to be right.

Each one names, at the top of this file, what killed it.

CLOUD-X-issue-326-planner-shape.md — withdrawn 2026-08-25

Drafted as CLOUD-4 of the 25 August batch. Withdrawn after the batch's own truth-check fan-out refuted three of its claims:

1. **Its measurements were eighteen days stale.** It cited `planner.rs` at 6,244 lines and `shape()` at 614 lines holding 22 match arms, from the issue's 2026-08-05 measurement. Actual state on 25 August: `planner.rs` is **3,376** lines — commit `50350e5b` extracted 23 local executors into seven domain modules on 23 August — and `shape()` is **~798 lines holding 31 arms**, having grown as new operations landed. Both numbers moved, in opposite directions, and the handoff was confident about both.
2. **Issue #326 explicitly forbids the approach the handoff instructed.** Its own words: *"Do NOT do this as a single large refactor... `planner.rs` is the most contended file in the repo... a big-bang move maximises conflict against in-flight branches."* Its recommended approach is milestone-tied and incremental — *"when a milestone touches an operation, move that operation's*

`shape()` *arm into its per-operation module at the same time* — with no deadline. Splitting the sweep into per-arm commits, as the handoff proposed, does not answer that objection: it is still one dedicated sweep landing in one PR.

3. **The contention the issue warned about was live inside this very batch.** CLOUD-2 (#493/#494) also edits `planner.rs` and `planner/stash.rs`. The one argument that might have excused a big-bang move for a cloud batch — that cloud sessions do not collide with in-flight local branches — did not hold, because the collision was with another member of the same batch.

What replaced it: #438, the process-global test race, which had failed CI that same morning and collides with nothing.

What #326 needs instead: nothing, for now. It is working as designed — a standing instruction to move an arm when a milestone touches its operation. The corrected measurements were posted to the issue so the next reader does not inherit the stale ones.
